Lecture 1: relational structures, modal languages, frames and models

September 6, 2016

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

An old definition:

Modal logic is the logic of necessity and possibility.

- $\Box p$: the proposition p is necessarily true
- $\Diamond p$: the propostion p might possibly be true

Paradoxes of material implication

• p
ightarrow (q
ightarrow p)

•
$$\neg p
ightarrow (p
ightarrow q)$$

•
$$(p
ightarrow q) \lor (q
ightarrow p)$$

Strict implication:

$$p \Rightarrow q = \Box(p \rightarrow q)$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

Philosophy as *conceptual analysis*. Other readings of the box:

• p will be true some time in the future (temporal logic)

- p is known to be true (epistemic logic)
- *p* is believed to be true (doxastic logic)
- *p* ought to be true (deontic logic)

Intensional/non-truth functional connectives.

Semantics

The purpose of semantics is to assign *interpretations* of the logical symbols occurring in formulas. Early semantics of modal logics were *algebraic*.

A paradigm shift occurred when Saul Kripke introduced *relational semantics*, now called *Kripke semantics*. The origin of relational semantics comes from Leibniz' analysis of necessity as *truth across all possible worlds*.

A more up-to-date definition:

Modal logics are formal languages for describing and reasoning about relational structures, often combining simplicity and good computational properties with expressive power.

- Philosophy (logics of necessity, knowledge, time, obligations...)
- Mathematics (provability logic, logics for topology, connections with set theory...)
- Computer science (temporal and dynamic logics, description logic...)

• Many more, and still expanding...

A relational structure is a structure $(W, \{R_i\}_{i \in I})$ where W is a set and $\{R_i\}_i \in I$ is a family of relations, each with a given *arity*.

Familiar examples of relational structures are $(\mathbb{N}, <)$, $(\mathbb{Z}, <)$, $(\mathbb{Q}, <)$ and $(\mathbb{R}, <)$. We get another family of relational structures by putting \leq in the place of <.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

 (\mathbb{N}, R) where:

$$R = \{ \langle i, j, k \rangle \in \mathbb{N}^3 \mid i = j + k \}$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

 $\langle 8,3,5\rangle \in \textit{R}, \ \langle 3,10,4\rangle \notin \textit{R}...$

The *full binary tree* is the set of all finite words over $\{0,1\}$. For example, 00101 is a member of the full binary tree, as is the empty word. It is a relational structure (T, succ) where succ is the *successor relation*.

Rabin's theorem, "mother of all decidability results".

A tree is a relational structure (W, R) with a distinguished root r such that, for all $w \in W$, there is a unique R-path from r to w.

Labelled transition systems, used extensively in computer science, are relational structures $(W, \{R_a\}_{a \in A})$ where $R_a xy$ holds iff there is an edge from x to y labelled a.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

The Euclidean plane is a relational structure with a ternary relation C defined as: C(x, y, z) iff x is closer to y than to z with respect to the Euclidean distance.

Let R be a binary relation on a set W. Then R is said to be:

- reflexive if ∀xRxx
- *irreflexive* if $\forall x \neg Rxx$
- transitive if $\forall x, y, z(Rxy \land Ryz \rightarrow Rxz)$
- symmetric if $\forall x, y(Rxy \rightarrow Ryx)$
- anti-symmetric if $\forall x, y (Rxy \land Ryx \rightarrow x = y)$
- connected or total if $\forall xy(Rxy \lor Ryx)$

R is:

- A pre-order if it is reflexive and transitive
- A partial order if it is a pre-order and anti-symmetric
- A total order if it is a partial order and total.
- A strict total order if it is irreflexive, transitive and total.

• An *equivalence relation* if it is reflexive, transitive and symmetric.

Proposition

There is a one-to-one correspondence between the equivalence relations on any set W and the partitions of W.

Basic modal language

$$\varphi := \pmb{p} \mid \bot \mid \varphi \lor \varphi \mid \neg \varphi \mid \Diamond \varphi$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

•
$$\top = \neg \bot$$

- $\varphi \wedge \psi = \neg (\neg \varphi \vee \neg \psi)$
- $\varphi \rightarrow \psi = \neg (\varphi \land \neg \psi)$
- $\bullet \ \Box \varphi = \neg \Diamond \neg \varphi$

A frame \mathfrak{F} for the basic modal language is a relational structure (W, R) where R is a binary relation.

Definition

A model \mathfrak{M} for the basic modal language is a triple (W, R, V) such that (W, R) is a frame and $V : Var \rightarrow \mathcal{P}(W)$ a valuation.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Truth clauses:

- $\mathfrak{M}, w \Vdash \bot$ never,
- $\mathfrak{M}, w \Vdash p$ iff $w \in V(p)$,
- $\mathfrak{M}, w \Vdash \varphi \lor \psi$ iff $\mathfrak{M}, w \Vdash \varphi$ or $\mathfrak{M}, w \Vdash \psi$,
- $\mathfrak{M}, w \Vdash \neg \varphi$ iff $\mathfrak{M}, w \nvDash \varphi$,
- $\mathfrak{M}, w \Vdash \Diamond \varphi$ iff $\mathfrak{M}, v \Vdash \varphi$ for some v, wRv.

Crucial property of modal logic: formulas are evaluated "locally". Think of formulas as *automata*!

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

A formula is *globally* true on $\mathfrak{M}, \mathfrak{M} \Vdash \varphi$, if $\mathfrak{M}, w \Vdash \varphi$ for all $w \in W$. A formula is *valid* on \mathfrak{F} if $\mathfrak{F}, V \Vdash \varphi$ for all valuations V.

A similarity type is a pair (O, τ) where O is a set of operator symbols and $\tau : O \to \omega$.

Modal language for (O, τ)

$$p \mid \perp \mid \varphi \lor \varphi \mid \neg \varphi \mid \Delta(\varphi_1, ..., \varphi_n)$$

where $\Delta \in O$, $\tau(\Delta) = n$.

$$\nabla(\varphi_1,...,\varphi_n) = \neg \Delta(\neg \varphi_1,...,\neg \varphi_n)$$

A frame for similarity type (O, τ) is a pair $(W, \{R_{\Delta}\}_{\Delta \in O})$ where each R_{Δ} is a $\tau(\Delta) + 1$ -ary relation on W.

Definition

Model = frame plus valuation, same as before.

Truth clauses:

- $\mathfrak{M}, w \Vdash \bot$ never,
- $\mathfrak{M}, w \Vdash p$ iff $w \in V(p)$,
- $\mathfrak{M}, w \Vdash \varphi \lor \psi$ iff $\mathfrak{M}, w \Vdash \varphi$ or $\mathfrak{M}, w \Vdash \psi$,
- $\mathfrak{M}, w \Vdash \neg \varphi$ iff $\mathfrak{M}, w \nvDash \varphi$,
- $\mathfrak{M}, w \Vdash \Delta(\varphi_1, ..., \varphi_n)$ iff

 $\mathfrak{M}, \mathbf{v}_1 \Vdash \varphi_1 \& \dots \& \mathfrak{M}, \mathbf{v}_n \Vdash \varphi_n$

for some v_1, \ldots, v_n , $Rwv_1 \ldots v_n$.

Truth clause for ∇ ?

Basic temporal language

 $O = \{F, P\}$, both unary. Duals: G, H.

- Will be the case in the <u>F</u>uture.
- Was the case in the <u>P</u>ast.
- Always <u>G</u>oing to be the case.

• Always <u>H</u>as been the case.

Suitable frames for the basic temporal language

- (N, <): time is *discrete* and has a *beginning* but *no end*.
- $(\mathbb{Z}, <)$: time is *discrete* and *endless* in both directions.
- $(\mathbb{Q}, <)$: time is *dense*.
- $(\mathbb{R}, <)$: time is *Dedekind complete* (has no "gaps").

Temporal formulas:

- $p \rightarrow \mathsf{GP}p$ (all)
- $p \rightarrow \mathsf{HF}p$ (all)
- $Hp \rightarrow Pp \text{ (not } \mathbb{N})$
- $\mathsf{F}p \to \mathsf{FF}p \text{ (not } \mathbb{N} \text{ or } \mathbb{Z})$

▲□▶ ▲圖▶ ★ 国▶ ★ 国▶ - 国 - のへで

Epistemic logic

 $O = \{\mathsf{K}_a\}_{a \in \mathcal{A}}$, all operators unary. $\mathsf{K}_a \varphi$ read "a knows that φ ".

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Traditional frames: equivalence relations.

Equivalently, *partitions* of spaces of possible situations.

A model of epistemic logic

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

Some epistemic formulas:

- $K_a \varphi \rightarrow \varphi$ (valid)
- $K_a \varphi \rightarrow K_b K_a \varphi$ (not valid)
- $K_a \varphi \rightarrow K_a K_a \varphi$ (valid)
- $\neg K_a \varphi \rightarrow K_a \neg K_a \varphi$ (valid)

There is room for philosophical discussion here! Which formulas *should* be valid on reasonable models of knowledge?

Traditional analysis:

Knowledge = true, justified belief.

Example

Bob is a member of the Flat Earth Society. It is not *true* that the Earth is flat and he is not *justified* in believing so. Hence he doesn't know it. But he doesn't believe that he doesn't know it, so he doesn't *know that he doesn't know* either!

Propositional dynamic logic of regular programs

O consists of terms in the language of *regular expressions* built over a set of atoms *A*:

 $a \mid \pi; \pi \mid \pi \cup \pi \mid \pi^*$

Each term is viewed as a unary operator.

Diamond \Diamond_{π} usually written as $\langle \pi \rangle$.

Floyd-Hoare logic

$\{\varphi\}\pi\{\psi\}$

"If pre-condition φ holds, then after execution of the program π the post-condition ψ will hold".

In PDL:

 $\varphi \to [\pi] \psi$

The following should be valid according to the intended interpretation:

- $\langle \pi_1; \pi_2 \rangle p \leftrightarrow \langle \pi_1 \rangle \langle \pi_2 \rangle p$
- $\langle \pi_1 \cup \pi_2 \rangle p \leftrightarrow (\langle \pi_1 \rangle p \lor \langle \pi_2 \rangle p)$
- $\langle \pi^* \rangle p \leftrightarrow (p \lor \langle \pi; \pi^* \rangle p)$ (fixed point formula)

Segerberg's induction axiom

$$[\pi^*](
ho
ightarrow [\pi]
ho)
ightarrow (
ho
ightarrow [\pi^*]
ho)$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

- Test (φ?): stay in the same state if φ is true, otherwise terminate with no output.
- Intersection: $(\pi_1 \cap \pi_2)$: run both programs π_1 and π_2 in parallell.

Examples:

$$(p?; a) \cup (\neg p?; b) = \text{if } p \text{ do } a \text{ else } b$$

 $(p?; a)^*; \neg p? = \text{while } p \text{ do } a$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Many structures involve objects that can be visualized as "arrows", that may have a *direction* in some sense and can be *composed*.

- Linear algebra (vectors, composition = vector addition)
- Category theory (morphisms, composition primitive)
- Formal language theory (words, composition = concatenation)

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

• Programs (composition = execution in sequence)

Language of arrow logic

 $O = \{C, I, \otimes\}$: ternary, nullary, binary.

- $R_C uvw$: *u* is the composition of *v* and *w*
- *R_Iu*: *u* is an "identity arrow" (zero vector, identity morphism, empty word, "skip" program...)

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

• $R_{\otimes}uv$: *u* is a converse of *v*

Some formulas of arrow logic

• $C(I,p) \rightarrow p$

•
$$C(p, I) \rightarrow p$$

•
$$I \leftrightarrow \otimes I$$

Simple frames are Cartesian squares.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

Validity and frame constraints

Given a reading of the box and diamond operators, some principles are more reasonable than others. On the semantic side, some frames are compatible with the intended reading while others are not. These two aspects are tightly related, and sets us on the path to *correspondence theory*.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

$$\mathsf{P}p o \mathsf{GP}p$$

 $\mathsf{F}p o \mathsf{HF}p$

Valid on frames satisfying:

 $\forall x \forall y (Rxy \leftrightarrow Ryx)$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへで

Other constraints on temporal frames

- $FFp \rightarrow Fp (PPp \rightarrow Pp)$. Valid on *transitive* temporal frames ("later than" and "earlier than" are transitive).
- $Fp \rightarrow FFp (Pp \rightarrow PPp)$. Valid on *dense* temporal frames.
- (Fp ∧ Fq) → (F(p ∧ Fq)) ∨ F(q ∧ Fp) ∨ F(p ∧ q)). Valid on temporal frames on which, for all x, y: xR_Fy ∨ yR_Fx ∨ x = y.

Note

We normally think of time as *continuous* and *deterministic*. But in computer science, "time" is frequently modelled as *discrete* and *branching*.

$\langle \langle \pi_1 \cup \pi_2 \rangle \boldsymbol{\rho} \leftrightarrow (\langle \pi_1 \rangle \boldsymbol{\rho} \vee \langle \pi_2 \rangle \boldsymbol{\rho})$

$$R_{\pi_1\cup\pi_2}=R_{\pi_1}\cup R_{\pi_2}$$

◆□▶ ◆圖▶ ◆臣▶ ◆臣▶ 臣 - のへで

$\langle \pi_1; \pi_2 \rangle p \leftrightarrow (\langle \pi_1 \rangle \langle \pi_2 \rangle p)$

$\forall x \forall y (R_{\pi_1;\pi_2} \leftrightarrow \exists z (R_{\pi_1} xz \land R_{\pi_2} zy))$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

Fixed point formula & induction axiom

$$R_{\pi^*} = R_{\pi}^*$$

Here, R^* is the *reflexive transitive closure* of R:

$$R^* = \bigcap \{ R' \mid R' \text{ ref. trans. } \& R \subseteq R' \}$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへで

A model constraint for Test

$\langle \varphi? \rangle p \leftrightarrow \varphi \wedge p$

$$R_{\varphi?} = \{(w, w) \mid w \Vdash \varphi\}$$

◆□> <圖> < E> < E> E のQQ

We haven't mentioned *logic* or *consequence* yet...

◆□ ▶ < 圖 ▶ < 圖 ▶ < 圖 ▶ < 圖 • 의 Q @</p>

A normal modal logic is a set $\mathfrak L$ of formulas closed under:

- Modus ponens: $\frac{\varphi \quad \varphi \rightarrow \psi}{\psi}$
- Uniform substitution: $\frac{\varphi}{\varphi[\sigma]}$
- Necessitation: $\frac{\varphi}{\Box \varphi}$

and containing the following formulas:

- The K-axiom: $\Box(p
 ightarrow q)
 ightarrow (\Box p
 ightarrow \Box q)$
- Dual: $\Diamond p \leftrightarrow \neg \Box \neg p$

Proposition

For every class F of frames, there is a normal modal logic Λ_F given by:

$$\varphi \in \Lambda_{\mathsf{F}} \quad \Leftrightarrow \quad \forall \mathfrak{F} \in \mathsf{F} : \mathfrak{F} \Vdash \varphi$$

Observe that:

$$\mathsf{K}_1 \subseteq \mathsf{K}_2 \quad \Rightarrow \quad \Lambda_{\mathsf{K}_2} \subseteq \Lambda_{\mathsf{K}_1}$$

▲□▶ ▲圖▶ ★ 国▶ ★ 国▶ - 国 - のへで

The logic $\Lambda_{[All \; frames]}$ is the smallest normal modal logic, and denoted by K...

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

... after Saul Kripke.

A formula φ is a *local consequence* of formulas Γ if, for any model \mathfrak{M} and $w \in W$:

```
\mathfrak{M}, w \Vdash \Gamma implies \mathfrak{M}, w \Vdash \varphi
```

```
Notation: \Gamma \vDash_I \varphi.
```

Definition

A formula φ is a *global consequence* of formulas Γ if, for any model \mathfrak{M} :

```
\mathfrak{M} \Vdash \Gamma implies \mathfrak{M} \Vdash \varphi
```

Notation: $\Gamma \vDash_{g} \varphi$.
