### Table of contents

#### Intro

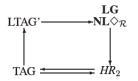

#### $LTAG_0$

definition difference with LTAG example; copylanguage

#### Conversion to LG

lexical conversion example; copylanguage graphical conversion example; copylanguage

Moot 2007 & LIRA-paper

- For each LTAG there is a weakly equivalent  $LTAG_0$ .
- For each  $LTAG_0$  there is a strongly equivalent LG.
- If *LTAG* is out of the context free boundary then so is *LG*.

#### What is an LTAG<sub>0</sub>

similar to a normal LTAG.

#### definition:

An  $LTAG_0$  grammar is a tuple  $\langle T, N_S, N_A, I, A \rangle$  such that:

- *T* is the finite set of terminals.
- $N_S$  is the finite set of the substitution non-terminals.
- $N_A$  is the finite set of the adjunction non-terminals.

- I is the finite set of the initial trees.
- A is the finite set of the auxiliary trees.

### What is an LTAG<sub>0</sub>

#### definition:

An  $LTAG_0$  grammar is a tuple  $\langle T, N_S, N_A, I, A \rangle$  such that:

#### conditions

- The root nodes of all initial trees are members of  $N_S$ .
- The root nodes of all auxiliary trees are members of  $N_A$ .

#### What is an LTAG<sub>0</sub>

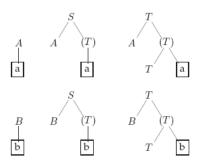

#### definition:

An  $LTAG_0$  grammar is a tuple  $\langle T, N_S, N_A, I, A \rangle$  such that:

#### conditions

- The root nodes of all initial trees are members of  $N_S$ .
- The root nodes of all auxiliary trees are members of  $N_A$ .
- (!) Every auxiliary tree has exactly one leaf which is a member of  $N_{A}$ . (foot node)
- ▶ (!) Every initial or auxiliary tree has exactly one leaf which is a member of T.
- (!) Every adjunction node is on the path from the lexical leaf to the root of the tree.

the copylanguage:  $\{ww | w \in \{a, b\}^+\}$ 

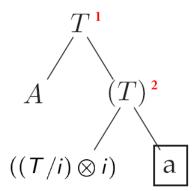

- (!) Every auxiliary tree has exactly one leaf which is a member of  $N_A$ . (foot node)
- (!) Every initial or auxiliary tree has exactly one leaf which is a member of T.
- (!) Every adjunction node is on the path from the lexical leaf to the root of the tree.

#### Constructing LG grammar g' from LTAG<sub>0</sub> g

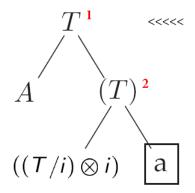

- The set of Atomic formulas A of g' will be  $N_A \cup N_S \cup \{i\}$
- Each initial or auxiliary tree in g will have a lexical type assignment in g' constructed from it.
- footnodes are given the type  $((T/i) \otimes i)$
- Then we start at the root R and travel down the tree to the lexical anchor, starting with as current formule f = R.
- If a binary link is passed, with a descendant A that does not lie on the path to the lexical anchor, f will be either A\f or f/A depending on whether A is the left or right descendent. If an adjunction node (T) is passed f will be (T ⊘ f) ⊗ ((T/i) ⊗ i)

 $LTAG_0$  to LG the copylanguage:  $\{ww | w \in \{a, b\}^+\}$ 

footnodes are given the type  $((T/i) \otimes i)$ We will construct the lexical type of a, while descending through the tree. While descending f will be the growing type.

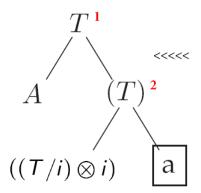

the copylanguage:  $\{ww | w \in \{a, b\}^+\}$ 

▲□▶ ▲圖▶ ▲臣▶ ▲臣▶ ―臣 … のへで

 $f = T^1$ 

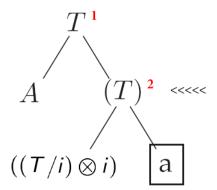

the copylanguage:  $\{ww | w \in \{a, b\}^+\}$ 

▲□▶ ▲圖▶ ▲臣▶ ▲臣▶ ―臣 … のへで

 $f = A \setminus T^1$ 

the copylanguage:  $\{ww | w \in \{a, b\}^+\}$ 

 $f = (T^2 \otimes (A \setminus T^1)) \oslash ((T^2/i) \otimes i)$ 

▲ロト ▲圖ト ▲屋ト ▲屋ト

æ

the copylanguage:  $\{ww | w \in \{a, b\}^+\}$ 

 $f = ((T/i) \otimes i) \setminus ((T^2 \otimes (A \setminus T^1)) \otimes ((T^2/i) \otimes i))$ 

・ロト ・聞 と ・ 聞 と ・ 聞 と …

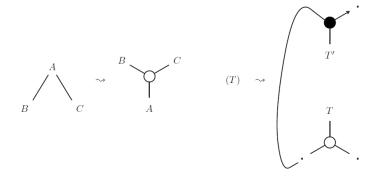

æ 👘

the copylanguage:  $\{ww | w \in \{a, b\}^+\}$ 

 $lex(a) = ((T/i) \otimes i) \setminus ((T^2 \otimes (A \setminus T^1)) \otimes ((T^2/i) \otimes i))$ Now we would like to abbreviate the  $((T^2/i) \otimes i)$  to T' Resulting in:  $lex(a) = T' \setminus ((T \otimes (A \setminus T)) \otimes T')$ 

#### graphical conversion; binary split & adjunction
